(54) Title: TUNABLE ANTENNA

(57) Abstract: The invention refers to an antenna comprising: a conducting trace (15, 20), said conducting trace (15, 20) defining a curve (1, 4, 5, 6, 6', 6'', 8), said curve (1, 4, 5, 6, 6', 6'', 8) including two or more feeding points (16a, 16b, 16c, 17, 18, 19), a portion of said curve (1, 4, 5, 6, 6', 6'', 8) being shaped according a geometry selected from a group of geometries including a space-filling curve, a grid-dimension curve, a box-counting curve and a contour

curve or the curve (1, 4, 5, 6, 6', 6'', 8) or a portion of said curve having a shape of a multilevel structure. Further the invention refers to a related SMD component, an IC-package, a wireless device and a method for contacting an antenna.

TUNABLE ANTENNA

This application is related to application number US60/613394 filed on September 27, 2004, in the U.S. and to application number US60/640380 filed on December 30, 2004 in the U.S. and claims priority to those applications, which are incorporated herein by reference.

The present invention relates to a tunable antenna.

Tunable antennae are desirable in order to have multiple operating frequencies, impedances, bandwidths or efficiencies available with one antenna only or to be able to compensate undesired frequency shifts, impedance shifts, bandwidth shifts or efficiency shifts or combinations of those effects.

One of the challenges of small SMD antenna devices is to provide a standard, low cost component that can be used throughout a wide range of products with many different form factors. Usually, the resonant frequency of the antenna changes with the interaction of the surrounding components (e.g., the ground of the PCB, the plastic covers, etc.)

This frequency change may render the device useless, since in communication systems the operating frequencies or at least ranges thereof are well defined and have to be maintained. It is therefore desirable to be able to compensate for such changes of the resonant frequency in order to maintain a particular resonant frequency or frequency band. In particular for the mass production of wireless devices, it is desirable to have one antenna type, that may be used for different wireless devices or may be used in one wireless device for different operating frequencies.

There is a trend in the semiconductor industry towards the so-called System on Chip (SoC) and System in Package (SiP) concepts. The full integration of systems or subsystems into a single chip (Fully Wireless System in Package/ on Chip, FWSiP/FWSoC) provides many advantages in terms of cost, size, weight, power consumption, performance, modularity and product design complexity. Several electronic devices for consumer applications, such as handsets, wireless devices (headsets, dongles, computer interfaces, computer mouse, keyboards, remote controls), personal digital assistants (PDAs) or personal computers (PCs) include more and more of these SiP/SoC components. The introduction of wireless capabilities in many other devices such as digital cameras, MP3 players, portable DVD/CD

players, smoke detectors, switches, sensors (such as for instance motion, pressure, temperature, medical sensors and meters) and alarms will be made easier through such compact, integrated SiP/SoC devices.

It is therefore an object of the present invention to provide an improved antenna, an improved SMD component, an improved IC-package, an improved wireless device and an improved method of contacting an antenna.

This problem is solved for instance by the antenna of claim 1, the SMD component of claim 21 or 22, the IC package of claim 42, the wireless device of claim 62, the wireless device of claim 74, the wireless device of claim 86 or the method of claim 100. Preferred embodiments are disclosed in the dependent claims.

The antenna comprises a conducting trace, which may be contacted by two or more feeding points. Depending on the contacted feeding point or the combination of contacted feeding points, the resonant frequency, the impedance, the bandwidth or the efficiency of the antenna is different. Thereby it is possible to tune the antenna by the way the antenna is contacted.

In accordance with the teachings described herein, systems and methods are provided for an antenna having multiple feed points that may be used to adjust characteristics of the antenna such as resonant frequency, impedance, bandwidth, and efficiency. The antenna may, for example, be integrated in a surface mount component (SMD/SMT) to be mounted on a ground plane or (printed) circuit board (PCB). (The terms SMD component (surface mount device component) and SMT component (surface mount technology component) both refer to the same and are used equally to describe components which may be surface mount). The antenna may, for example, be printed directly on the PCB of an electronic circuit or wireless device. In addition, the antenna may, for example, be embedded in an integrated circuit package or module that includes other parts of a wireless or radio frequency system.

The antenna described herein may, for example, be used in a wide range of wireless products with many different form factors, such as cellular and handheld telephones (handsets), wireless multimedia terminals, PDAs, portable music players (e.g., MP3 players, CD players, portable analog and digital radios), digital cameras, USB dongles, wireless headsets and earphones, hands-free kits, electronic games, remote controls, light switches, alarms and sensors for home-RF and automotive applications. In addition, the antenna

described herein may be used for wireless connectivity applications, including systems for communicating in various frequency bands, such as 2.4 GHz, Bluetooth, 2.4 GHz, IEEE 802.11 b/g, 5 GHz, IEEE 802.11 a, ZigBee, GPS, Galileo, GSM-900, DCS-1800, UMTS, CDMA, DAB, or other bands. The antenna described herein may, for example, also be used in several geographical domains where the spectrum allocation for radio services are different (e.g., the antenna may cover the 860MHz ZigBee European band or the 915 MHz ZigBee US band.) It should be understood, however, that other applications are also possible. The shape of the conducting trace is predetermined by the antenna structure. Thereby the antenna properties are mainly predetermined by the given shape.

In many cases, the ultimate component to achieve the true integration of a FWSiP/FWSoc component is the antenna. The concept of integrating a miniature antenna into a package or module is especially attractive due to the tremendous growth and success of cellular and wireless systems. In particular, there is a new generation of short/medium range wireless connectivity applications such as Bluetooth™, Hyperlan, IEEE802.11 (WiFi), ultra wide band (UWB), Wimax and ZigBee systems where the progressive system integration into a single, compact product is becoming a key success factor.

One of the challenges of FWSiP/FWSoc devices is to provide a standard solution that can be used throughout a wide range of products with many different form factors. Usually, the resonant frequency of the antenna changes with the interaction of the surrounding components (mainly the size and shape of the ground plane of the PCB, position on the PCB on which it is mounted, the ground plane clearance, the presence of plastic covers, and so on). The technology described herein presents ways to overcome this problem by providing an IC package with an integrated antenna that can be configured to perform well in many different environments.

The technology described herein provides a miniature antenna integrated into an IC package or module. The IC package or module may, for example, be used as a connectivity solution in several wireless connectivity applications. For instance, the IC package or module described herein may include an antenna that operates in the following systems and frequency bands: 2.4 GHz - Bluetooth™, 2.4 GHz - IEEE 802.11b/g, 5 GHz - IEEE 802.11a, ZigBee, GPS, Galileo, GSM-900, DCS-1800, UMTS, CDMA, PCS1900, KPCS, WCDMA and DAB bands.

In addition, the configurability and/or tunability of the antenna integrated in the IC package may provide a single FWSiP/FWSoC solution that can be used in several geographical domains where the spectrum allocation for radio services are different. For instance, in one example the antenna can be tuned to cover the European band or US band of ZigBee (860MHz and 915 MHz respectively), while in another example the same AiP (Antenna in Package) module can cover either the 2.4 – 2.483GHz band or the 2.471 – 2.497GHz band, corresponding to the US/European and Japanese standards of Bluetooth™ respectively.

In a preferred embodiment at the feeding point, means for electrically contacting the conducting trace are provided in order to facilitate the antenna mounting. The means for electrically contacting the conducting trace may be anything that distinguishes from the trace itself and allows for contacting the trace.

In a preferred embodiment the trace may be comprised of a rigid piece and/or may be held by a rigid backing. Different materials for the rigid piece or rigid, stiff or solid backing are possible, as disclosed in the description or the claims. The rigid piece may be a stamped or punched piece of metal that maintains its shape already only due its own stiffness.

In a preferred embodiment, the antenna is provided directly on a circuit board, e.g. by printing or by etching from a conductive layer, or by a thick film process, or a thin film process. The advantage of the antenna being provided directly on the circuit board is the improved fabrication process, since the antenna may be prepared together with other circuitry.

The antenna may have one, two, three or more radiating arms. While only one radiating arm has the advantage of the possibility to use the given space with one single lengthy trace, the provision of more radiating arms offers the advantage to have more freedom in the antenna design, since the antenna geometry can be used to define, e.g., the resonant frequency, impedance, bandwidth and efficiency.

The trace may be continuous or discontinuous. Should the trace be discontinuous, the parts of the trace at the discontinuity may be not directly coupled by contact, but electromagnetically coupled by electromagnetic fields. The option of a discontinuous antenna allows for further design parameters in antenna design.

The conducting trace may comprise several separated parts or blocks. Each of those parts or blocks may have at least one, two, three or more feeding points. This allows for a very flexible system, where antenna properties can be varied to a great extent. It is for example possible to only contact one or the other of said separated parts. Since each separated part may have different antenna properties this allows for an appropriate selection. Further it is possible to connect two, three or more separated parts together allowing for all kind of antenna configurations such as a monopole, a dipole, an antenna with multiple radiation arms, etc. The length of the different arms can be selected by the choice of one or the other separated part or by connecting two or more parts together. Some or all of the separated parts may be different. The different parts may be connected together by e.g. an external bypass or an external circuit, a switch, a switchable transistor or resistor, a filter, a matching network, an inductive, capacitive or generally passive network or by an active network or anything suitable. This allows for further antenna design options. For the connection of two separated parts also more than one of the above mentioned ways may be available. Two parts may e.g. be connected by a switch or by a network depending on the users selection.

A further possibility for designing the antenna properties is to couple the trace to another antenna structure, such as e.g. a polygonal or multilevel surface. Such surfaces may be coupled by direct contact or by electromagnetic coupling. This other antenna structure is preferably conducting or dielectric.

In a preferred embodiment the trace, or at least part of the trace, is covered by an insulator. This facilitates handling and mounting of the antenna, protects the conducting trace and further prevents the conducting trace from changing its electric properties due to protection of the conducting trace from environmental influences such as humidity, or aggressive gases. Further, by covering the trace, or at least part of the trace with an insulator, the surrounding of the antenna very close to the antenna is electromagnetically provided in a well-defined way, such that the electromagnetic properties of the antenna do not change so easily by providing the antenna in different environments. Further the insulator defines openings to the feeding points which may be e.g. configured for soldering in order to define the soldered areas. Different materials as disclosed in the description or in the claims may be used for the insulator.

At the feeding points the trace is preferably uncovered. This allows for easy contacting of the trace at the feeding points. The feeding points may alternatively also be covered by an easily removable cover such as a foil or the like. This cover may also cover part of the insulator. A

single cover may be used for different feeding points. The cover offers the advantage of protecting the feeding points up to, e.g., mounting the antenna.

The antenna may be provided together with an integrated circuit. This integrated circuit may be adapted to feed the antenna and/or to contact the antenna or to connect separated parts of the antenna. The integrated circuit may provide other functions such as data processing for data transmission or data reception according to one, two or more specific data communication system.

The antenna may be provided in the conductive layer of a circuit board, wherein this conductive layer is also used to provide the contacts to the integrated circuit. The antenna may also be provided as an item which is mounted to a circuit board on which also the integrated circuit is mounted. The antenna and the integrated circuit may be provided on the same side of a circuit board or substrate or on opposite sides. Here via holes may be provided e.g. to connect the antenna and the integrated circuit.

The integrated circuit and the conducting trace may be connected in various ways such as by at least an external connection, an internal connection, a circuit board trace, an electrical circuit, a capacitive device, an inductive device, a switch, a transistor, a wire bond and a (switchable) resistor. These and other options allow for a great flexibility when combining the integrated circuit and the antenna.

In some cases it may be advantageous to have the integrated circuit well separated from (but preferably still within one and the same package as) the antenna, since the antenna radiation may be absorbed by the integrated circuit and/or may disturb the circuits functioning. In this case the conducting trace is preferably not covered by said integrated circuit. In order to reduce the size it may, however, be advantageous or necessary to partially cover the conducting trace with the integrated circuit.

It is of particular advantage if the integrated circuit covers at least some or all of the feeding points of the conducting trace. Thereby it is possible to mount the integrated circuit directly on the feeding points, e.g. by soldering. The electrical connection between the antenna and the integrated circuit is thereby achieved in a relatively easy way. Due to the above mentioned radiation absorption it is further of advantage if the integrated circuit only covers the feeding points or at most the antenna portions next to the feeding points but does not cover the major part of the conducting trace.

For a proper functioning of the antenna, a proper connection of the antenna, and well defined electrical properties of such connection, may be important due to the electrical matching requirements. Here it may be advantageous to contact some or all of the feeding points at the fabrication of the antenna such that the connection is well defined. Here also after the connection tests may be performed to check for the properties of the connection. In order to select the appropriate feeding point one or more of the connections may be removed e.g. by scratching, drilling, laser ablation or the like depending on the type of connection. An antenna with small feeding points may e.g. be provided with wire bonds which connect the small feeding points to larger solder pads, pins or to contacts to an integrated circuit. Those wire bonds may be removed such that only the desired connections remain. Also by removal of a conducting trace on a circuit board by scratching, drilling or laser ablation only the desired connections may be maintained. Those connections, however, have well defined properties and therefore may not depend on the particular and unknown connection process performed by a user.

The curve defined by the conducting trace, may have a complex geometry. Possible geometries include the geometry of a space-filling curve, of a grid-dimension curve, of a box-counting curve, and of a contour-curve or the shape of a multilevel structure.

Those different geometries do not exclude each other. This means that, e.g., a space-filling curve may at the same time be a grid-dimension, a box counting, and a contour-curve, and all other ways around. Also multilevel structures and the other geometries do not exclude each other.

The complex geometry allows e.g. for multiple operating frequencies of one antenna only (even without use of the different feeding points, i.e. additional to the possibility given by the different feeding points) and further allows for a small antenna.

In a preferred embodiment the maximum extension of the conducting trace (determined by the diameter of the smallest sphere completely enclosing the conducting trace) is less than $1/5$ or $1/7$ or $1/10$ or $1/15$ or $1/20$ of the free space wavelength of the resonant (operating) frequency.

This criteria can also be used to define the terms space-filling curve, box-counting curve, grid dimension curve or contour curve. This means, that any curve with a maximum

extension less than $1/5$ or $1/7$ or $1/10$ or $1/15$ or $1/20$ of the free space wavelength of the resonant (operating) frequency can be said to be a space filling curve, a box counting curve, a grid dimension curve or a contour curve.

The different geometries are discussed in the following.

Space Filling Curves

In one example, the antenna or one or more of the antenna elements or antenna parts may be miniaturized by shaping at least a portion of the conducting trace (e.g., a part of the arms of a dipole, the perimeter of the patch of a patch antenna, the slot in a slot antenna, the loop perimeter in a loop antenna, or other portions of the antenna) as a space-filling curve (SFC). Examples of space filling curves are shown in Fig. 1b (see curves 1501 to 1514). A SFC is a curve that is large in terms of physical length but small in terms of the area in which the curve can be included. Space filling curves fill the surface or volume where they are located in an efficient way while keeping the linear properties of being curves. In general space filling curves may be composed of straight, essentially straight and/or curved segments. More precisely, for the purposes of this patent document, a SFC may be defined as follows: a curve having at least five segments that are connected in such a way that each segment forms an angle with any adjacent segments, such that no pair of adjacent segments define a larger straight segment. In addition, a SFC does not intersect with itself at any point except possibly the initial and final point (that is, the whole curve can be arranged as a closed curve or loop, but none of the lesser parts of the curve form a closed curve or loop).

A space-filling curve can be fitted over a flat or curved surface, and due to the angles between segments, the physical length of the curve is larger than that of any straight line that can be fitted in the same area (surface) as the space-filling curve. Additionally, to shape the structure of a miniature antenna, the segments of the SFCs should be shorter than at least one fifth of the free-space operating wavelength, and possibly shorter than one tenth of the free-space operating wavelength. The space-filling curve should include at least five segments in order to provide some antenna size reduction, however a larger number of segments may be used. In general, the larger the number of segments and the narrower the angles between them, the smaller the size of the final antenna.

A SFC may also be defined as a non-periodic curve including a number of connected straight or essentially straight segments smaller than a fraction of the operating free-space

wave length, where the segments are arranged in such a way that no adjacent and connected segments form another longer straight segment and wherein none of said segments intersect each other.

In one example, an antenna geometry forming a space-filling curve may include at least five segments, each of the at least five segments forming an angle with each adjacent segment in the curve, at least three of the segments being shorter than one-tenth of the longest free-space operating wavelength of the antenna. Preferably each angle between adjacent segments is less than 180° and at least two of the angles between adjacent sections are less than 115°, and at least two of the angles are not equal. The example curve fits inside a rectangular area, the longest side of the rectangular area being shorter than one-fifth of the longest free-space operating wavelength of the antenna. Some space-filling curves might approach a self-similar or self-affine curve, while some others would rather become dissimilar, that is, not displaying self-similarity or self-affinity at all (see for instance 1510, 1511, 1512).

Box-Counting Curves

In another example, the antenna or one or more of the antenna elements or antenna parts may be miniaturized by shaping at least a portion of the conducting trace to have a selected box-counting dimension. For a given geometry lying on a surface, the box-counting dimension is computed as follows. First, a grid with rectangular or substantially squared identical boxes of size L1 is placed over the geometry, such that the grid completely covers the geometry, that is, no part of the curve is out of the grid. The number of boxes N1 that include at least a point of the geometry are then counted. Second, a grid with boxes of size L2 (L2 being smaller than L1) is also placed over the geometry, such that the grid completely covers the geometry, and the number of boxes N2 that include at least a point of the geometry are counted. The box-counting dimension D is then computed as:

$$D = - \frac{\log(N2) - \log(N1)}{\log(L2) - \log(L1)}$$

For the purposes of this document, the box-counting dimension may be computed by placing the first and second grids inside a minimum rectangular area enclosing the conducting trace of the antenna and applying the above algorithm. The first grid in general has n x n boxes and the second grid has 2n x 2n boxes matching the first grid. The first grid should be chosen such that the rectangular area is meshed in an array of at least 5 x 5 boxes or cells, and the second grid should be chosen such that L2 = 1/2 L1 and such that the second grid

includes at least 10×10 boxes. The minimum rectangular area is an area in which there is not an entire row or column on the perimeter of the grid that does not contain any piece of the curve. Further the minimum rectangular area preferably refers to the smallest possible rectangle that completely encloses the curve or the relevant portion thereof.

An example of how the relevant grid can be determined is shown in Fig. 1 c to 1 e. In Fig. 1 c a box-counting curve is shown in it smallest possible rectangle that encloses that curve. The rectangle is divided in a $n \times n$ (here as an example 5×5) grid of identical rectangular cells, where each side of the cells corresponds to $1/n$ of the length of the parallel side of the enclosing rectangle. However, the length of any side of the rectangle (e.g. L_x or L_y in Fig. 1 d) may be taken for the calculation of D since the boxes of the second grid (see Fig. 1 e) have the same reduction factor with respect to the first grid along the sides of the rectangle in both directions (x and y direction) and hence the value of D will be the same no matter whether the shorter (L_x) or the longer (L_y) side of the rectangle is taken into account for the calculation of D . In some rare cases there may be more than one smallest possible rectangle. In this case the smallest possible rectangle giving the smaller value of D is chosen.

Alternatively the grid may be constructed such that the longer side (see left edge of rectangle in Fig. 1 c) of the smallest possible rectangle is divided into n equal parts (see L_1 on left edge of grid in Fig. 1 f) and the $n \times n$ grid of squared boxes has this side in common with the smallest possible rectangle such that it covers the curve or the relevant part of the curve. In Fig. 1 f the grid therefore extends to the right of the common side. Here there may be some rows or columns which do not have any part of the curve inside (See the ten boxes on the right hand edge of the grid in Fig. 1 f). In Fig. 1 g the right edge of the smallest rectangle (See Fig. 1 c) is taken to construct the $n \times n$ grid of identical square boxes. Hence, there are two longer sides of the rectangular based on which the $n \times n$ grid of identical square boxes may be constructed and therefore preferably the grid of the two first grids giving the smaller value of D has to be taken into account.

If the value of D calculated by a first $n \times n$ grid of identical rectangular boxes (Fig. 1 d) inside of the smallest possible rectangle enclosing the curve and a second $2n \times 2n$ grid of identical rectangular boxes (Fig. 1 e) inside of the smallest possible rectangle enclosing the curve and the value of D calculated from a first $n \times n$ grid of squared identical boxes (see Fig. 1 f or Fig. 1 g) and a second $2n \times 2n$ grid of squared identical boxes where the grid has one side in

common with the smallest possible rectangle, differ, then preferably the first and second grid giving the smaller value of D have to be taken into account.

Alternatively a curve may be considered as a box counting curve if there exists no first $n \times n$ grid of identical square or identical rectangular boxes and a second $2n \times 2n$ grid of identical square or identical rectangular boxes where the value of D is smaller than 1.1, 1.2, 1.25, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, or 2.9.

In any case, the value of n for the first grid should not be more than 5, 7, 10, 15, 20, 25, 30, 40 or 50.

The desired box-counting dimension for the curve may be selected to achieve a desired amount of miniaturization. The box-counting dimension should be larger than 1.1 in order to achieve some antenna size reduction. If a larger degree of miniaturization is desired, then a larger box-counting dimension may be selected, such as a box-counting dimension ranging from 1.5 to 2 for surface structures, while ranging up to 3 for volumetric geometries. For the purposes of this patent document, curves in which at least a portion of the geometry of the curve or the entire curve has a box-counting dimension larger than 1.1 may be referred to as box-counting curves.

For very small antennas, for example antennas that fit within a rectangle having a maximum size equal to one-twentieth the longest free-space operating wavelength of the antenna, the box-counting dimension may be computed using a finer grid. In such a case, the first grid may include a mesh of 10×10 equal cells, and the second grid may include a mesh of 20×20 equal cells. The grid-dimension (D) may then be calculated using the above equation.

In general, for a given resonant frequency of the antenna, the larger the box-counting dimension, the higher the degree of miniaturization that will be achieved by the antenna.

One way to enhance the miniaturization capabilities of the antenna (that is, reducing size while maximizing bandwidth, efficiency and gain) is to arrange the several segments of the curve of the antenna pattern in such a way that the curve intersects at least one point of at least 14 boxes of the first grid with 5×5 boxes or cells enclosing the curve. If a higher degree of miniaturization is desired, then the curve may be arranged to cross at least one of the boxes twice within the 5×5 grid, that is, the curve may include two non-adjacent portions inside at least one of the cells or boxes of the grid. The relevant grid here may be any of the

above mentioned constructed grids or may be any grid. That means if any 5 x 5 grid exists with the curve crossing at least 14 boxes or crossing one or more boxes twice the curve may be said to be a box counting curve.

Figure 1a illustrates an example of how the box-counting dimension of a curve 1 is calculated. The example curve 1 is placed under a 5 x 5 grid 2 (Fig. 1 a upper part) and under a 10 x 10 grid 3 (Fig. 1 a lower part). As illustrated, the curve 1 touches $N_1=25$ boxes in the 5 x 5 grid 2 and touches $N_2=78$ boxes in the 10 x 10 grid 3. In this case, the size of the boxes in the 5 x 5 grid 2 is twice the size of the boxes in the 10 x 10 grid 3. By applying the above equation, the box-counting dimension of the example curve 1 may be calculated as $D=1.6415$. In addition, further miniaturization is achieved in this example because the curve 1 crosses more than 14 of the 25 boxes in grid 2, and also crosses at least one box twice, that is, at least one box contains two non-adjacent segments of the curve. More specifically, the curve 1 in the illustrated example crosses twice in 13 boxes out of the 25 boxes.

The terms explained above can be also applied to curves that extend in three dimensions. If the extension in the third dimension is rather small the curve will fit into a $n \times n \times 1$ arrangement of 3D-boxes (cubes of size $L_1 \times L_1 \times L_1$) in a plane. Then the calculations can be performed as described above. Here the second grid will be a $2n \times 2n \times 1$ grid of cuboids of size $L_2 \times L_2 \times L_1$.

If the extension in the third dimension is larger a $n \times n \times n$ first grid and an $2n \times 2n \times 2n$ second grid will be taken into account. The construction principles for the relevant grids as explained above for two dimensions apply equally in three dimensions.

Grid Dimension Curves

In another example, the antenna or one or more antenna elements or antenna parts may be miniaturized by shaping at least a portion of the conducting trace to include a grid dimension curve. For a given geometry lying on a planar or curved surface, the grid dimension of the curve may be calculated as follows. First, a grid with substantially square identical cells of size L_1 is placed over the geometry of the curve, such that the grid completely covers the geometry, and the number of cells N_1 that include at least a point of the geometry are counted. Second, a grid with cells of size L_2 (L_2 being smaller than L_1) is also placed over the geometry, such that the grid completely covers the geometry, and the number of cells N_2

that include at least a point of the geometry are counted again. The grid dimension D is then computed as:

$$D = - \frac{\log(N2) - \log(N1)}{\log(L2) - \log(L1)}$$

For the purposes of this document, the grid dimension may be calculated by placing the first and second grids inside the minimum rectangular area enclosing the curve of the antenna and applying the above algorithm. The minimum rectangular area is an area in which there is not an entire row or column on the perimeter of the grid that does not contain any piece of the curve.

The first grid may, for example, be chosen such that the rectangular area is meshed in an array of at least 25 substantially equal preferably square cells. The second grid may, for example, be chosen such that each cell of the first grid is divided in 4 equal cells, such that the size of the new cells is $L2 = \frac{1}{2} L1$, and the second grid includes at least 100 cells.

Depending on the size and position of the squares of the grid the number of squares of the smallest rectangular may vary. A preferred value of the number of squares is the lowest number above or equal to the lower limit of 25 identical squares that arranged in a rectangular or square grid cover the curve or the relevant portion of the curve. This defines the size of the squares. Other preferred lower limits here are 50, 100, 200, 250, 300, 400 or 500. The grid corresponding to that number in general will be positioned such that the curve touches the minimum rectangular at two opposite sides. The grid may generally still be shifted with respect to the curve in a direction parallel to the two sides that touch the curve. Of such different grids the one with the lowest value of D is preferred. Also the grid whose minimum rectangular is touched by the curve at three sides (see as an example Fig. 1 f and Fig. 1 g) is preferred. The one that gives the lower value of D is preferred here.

The desired grid dimension for the curve may be selected to achieve a desired amount of miniaturization. The grid dimension should be larger than 1 in order to achieve some antenna size reduction. If a larger degree of miniaturization is desired, then a larger grid dimension may be selected, such as a grid dimension ranging from 1.5 - 3 (e.g., in case of volumetric structures). In some examples, a curve having a grid dimension of about 2 may be desired. For the purposes of this patent document, a curve or a curve where at least a portion of that curve is having a grid dimension larger than 1 may be referred to as a grid dimension curve.

In general, for a given resonant frequency of the antenna, the larger the grid dimension the higher the degree of miniaturization that will be achieved by the antenna.

One example way of enhancing the miniaturization capabilities of the antenna is to arrange the several segments of the curve of the antenna pattern in such a way that the curve intersects at least one point of at least 50% of the cells of the first grid with at least 25 cells (preferably squares) enclosing the curve. In another example, a high degree of miniaturization may be achieved by arranging the antenna such that the curve crosses at least one of the cells twice within the 25 cell grid (of preferably squares), that is, the curve includes two non-adjacent portions inside at least one of the cells or cells of the grid. In general the grid may have only a line of cells but may also have at least 2 or 3 or 4 columns or rows of cells.

Fig. 2 shows an example two-dimensional antenna forming a grid dimension curve with a grid dimension of approximately two. Fig. 3 shows the antenna of Fig. 2 enclosed in a first grid having thirty-two (32) square cells, each with a length L1. Fig. 4 shows the same antenna enclosed in a second grid having one hundred twenty-eight (128) square cells, each with a length L2. The length (L1) of each square cell in the first grid is twice the length (L2) of each square cell in the second grid ($L1 = 2 \times L2$). An examination of Fig. 3 and Fig. 4 reveal that at least a portion of the antenna is enclosed within every square cell in both the first and second grids. Therefore, the value of N1 in the above grid dimension (Dg) equation is thirty-two (32) (i.e., the total number of cells in the first grid), and the value of N2 is one hundred twenty-eight (128) (i.e., the total number of cells in the second grid). Using the above equation, the grid dimension of the antenna may be calculated as follows:

$$D_g = -\frac{\log(128) - \log(32)}{\log(2 \times L1) - \log(L1)} = 2$$

For a more accurate calculation of the grid dimension, the number of square cells may be increased up to a maximum amount. The maximum number of cells in a grid is dependent upon the resolution of the curve. As the number of cells approaches the maximum, the grid dimension calculation becomes more accurate. If a grid having more than the maximum number of cells is selected, however, then the accuracy of the grid dimension calculation begins to decrease. Typically, the maximum number of cells in a grid is one thousand (1000).

For example, Fig. 5 shows the same antenna as of Fig. 2 enclosed in a third grid with five hundred twelve (512) square cells, each having a length L_3 . The length (L_3) of the cells in the third grid is one half the length (L_2) of the cells in the second grid, shown in Fig. 4. As noted above, a portion of the antenna is enclosed within every square cell in the second grid, thus the value of N for the second grid is one hundred twenty-eight (128). An examination of Fig. 5, however, reveals that the antenna is enclosed within only five hundred nine (509) of the five hundred twelve (512) cells of the third grid. Therefore, the value of N for the third grid is five hundred nine (509). Using Fig. 4 and Fig. 5, a more accurate value for the grid dimension (D) of the antenna may be calculated as follows:

$$D_g = -\frac{\log(509) - \log(128)}{\log(2 \times L_2) - \log(L_2)} \approx 1.9915$$

It should be understood that a grid-dimension curve does not need to include any straight segments. Also, some grid-dimension curves might approach a self-similar or self-affine curves, while some others would rather become dissimilar, that is, not displaying self-similarity or self-affinity at all (see for instance Fig. 2).

The terms explained above can be also applied to curves that extend in three dimensions. If the extension in the third dimension is rather small the curve will fit into an arrangement of 3D-boxes (cubes) in a plane. Then the calculations can be performed as described above. Here the second grid will be composed in the same plane of boxes with the size $L_2 \times L_2 \times L_1$.

If the extension in the third dimension is larger a $m \times n \times o$ first grid and an $2m \times 2n \times 2o$ second grid will be taken into account. The construction principles for the relevant grids as explained above for two dimensions apply equally in three dimensions. Here the minimum number of cells preferably is 25, 50, 100, 125, 250, 400, 500, 1000, 1500, 2000, 3000, 4000 or 5000.

Contour curve

The contour-curve is defined by the ratio $Q = C/E$ given by the ratio of the length C of the circumference of the curve and of the largest extension E of said curve. The circumference is determined by all the borders (the contour) between the inside and the outside of the curve.

The largest extension E is determined by the diameter of the smallest circle, which encloses the curve entirely.

The more complex the curve, the higher the ratio Q. A high value of Q is advantageous in terms of miniaturization.

Examples of contour-curves are shown in Fig. 6. In Fig. 6a, left a line 4 composed of straight or almost straight pieces is shown which represents a contour curve. The circumference C of that curve 4 is shown in Fig. 6a, right. The curve of a real antenna will always have a certain line thickness, so that an inner part and an outer part is given such that the circumference is determined by the border between the inner part and the outer part of the curve. The circumference C has a length which corresponds to the double of the length of the curve 4, plus twice the line thickness of that curve. The largest extension E is also shown in Fig. 6a, right. The ratio Q is approximately 4.9.

In Fig. 6b, left a contour-curve 5 is shown which has an irregular shape. The hatched area is the area of the curve. The circumference and the largest extension E are shown in Fig. 6b, right. The circumference here also is given by the border between the inner and the outer part of the curve 5.

In Fig. 6c, left a contour-curve 6 (hatched) is shown which additionally has openings 7. The border of that openings 7 contribute to the length of the circumference C (see Fig. 6c. right).

In Fig. 6d a contour curve 6' (hatched area) with openings 7' is shown in which additionally in one of the openings a further curve piece 6'' (hatched) is shown, which is not in direct contact with the remainder 6' of the curve. Due to its proximity to the remainder 6' of the curve it is however electromagnetically coupled to the remainder 6' of the curve. The circumference of the piece 6'' also contributes to the length C of the circumference of the curve (see Fig. 6d, right).

If the curve is on a folded, bent or curved or otherwise irregular surface, or is provided in any another three-dimensional fashion (i.e. it is not planar), the ratio Q is determined by the length C of the circumference of the orthogonal projection of the curve onto a planar plane. The corresponding largest extension E is also determined from this projection onto the same planar plane. The plane preferably lies in such a way in relation to the three-dimensional

curve that the line, which goes along the largest extension F of the three-dimensional curve, lies in the plane (or a parallel and hence equivalent plane). The largest extension F of the three-dimensional curve lies along the line connecting the extreme points of the curve, which contact a sphere, which is given by the smallest possible sphere including the entire curve. Further the plane is oriented preferably in such a way, that the outer border of the projection of the curve onto the plane covers the largest possible area. Other preferred planes are those on which the value of C or Q of the projection onto that plane is maximized.

If for a three-dimensional curve a single projection plane is given in which the ratio Q of the projection of the curve onto the plane is larger than the specified minimal value, or this is the case for one of the above mentioned preferred projection planes the curve is said to be a contour curve. Possible minimum values for Q are 2.1, 2.25, 2.5, 2.75, 3.0, 3.1, 3.2, 3.25, 3.3, 3.5, 3.75, 4.0, 4.5, 5.0, 6, 7, 8, 9, 10, 12, 15, 20, 25, 30, 40, 50, 75, and 100.

In Fig. 6e an example of a three-dimensional contour curve 8 is shown. This curve is somehow undulated and shows holes 9. The projection of the curve 8 onto the planar plane 11 is shown with reference sign 10. The projection 10 includes openings corresponding to the holes 9. The ratio Q and the largest Extension E are to be determined from the projection 10. The plane 11 is chosen such that the outer border (not including the border of the holes 9) of the projection 10 covers the largest possible area onto that plane 11.

Another plane 12 is shown in Fig. 6e on which the curve 8 is orthogonally projected. The outer border of projection 13 on plane 12 covers an area significantly smaller than the outer border of projection 10 onto plane 11. The same applies to C and Q .

Multilevel Structures

In another example, at least a portion of the conducting trace of the antenna may be coupled, either through direct contact or electromagnetic coupling, to a conducting surface, such as a conducting polygonal or multilevel surface. Further the curve of the antenna or of the SMD component may include the shape of a multilevel structure. A multilevel structure is formed by gathering several geometrical elements such as polygons or polyhedrons of the same type or of different type (e.g., triangles, parallelepipeds, pentagons, hexagons, circles or ellipses as special limiting cases of a polygon with a large number of sides, as well as tetrahedral, hexahedra, prisms, dodecahedra, etc.) and coupling these structures to each other electromagnetically, whether by proximity or by direct contact between elements.

At least two of the elements may have a different size. However, also all elements may have the same or approximately the same size. The size of elements of a different type may be compared by comparing their largest diameter.

The majority of the component elements of a multilevel structure have more than 50% of their perimeter (for polygons) or of their surface (for polyhedrons) not in contact with any of the other elements of the structure. Thus, the component elements of a multilevel structure may typically be identified and distinguished, presenting at least two levels of detail: that of the overall structure and that of the polygon or polyhedron elements which form it.

Additionally, several multilevel structures may be grouped and coupled electromagnetically to each other to form higher level structures. In a single multilevel structure, all of the component elements are polygons with the same number of sides or are polyhedrons with the same number of faces. However, this characteristic may not be true if several multilevel structures of different natures are grouped and electromagnetically coupled to form meta-structures of a higher level.

A multilevel antenna includes at least two levels of detail in the body of the antenna: that of the overall structure and that of the majority of the elements (polygons or polyhedrons) which make it up. This may be achieved by ensuring that the area of contact or intersection (if it exists) between the majority of the elements forming the antenna is only a fraction of the perimeter or surrounding area of said polygons or polyhedrons.

One example property of a multilevel antennae is that the radioelectric behavior of the antenna can be similar in more than one frequency band. Antenna input parameters (e.g., impedance) and radiation patterns remain similar for several frequency bands (i.e., the antenna has the same level of adaptation or standing wave relationship in each different band), and often the antenna presents almost identical radiation diagrams at different frequencies. The number of frequency bands is proportional to the number of scales or sizes of the polygonal elements or similar sets in which they are grouped contained in the geometry of the main radiating element.

In addition to their multiband behavior, multilevel structure antennae may have a smaller than usual size as compared to other antennae of a simpler structure. (Such as those consisting of a single polygon or polyhedron). Additionally, the edge-rich and discontinuity-rich structure of a multilevel antenna may enhance the radiation process, relatively

increasing the radiation resistance of the antenna and reducing the quality factor Q , i.e. increasing its bandwidth.

A multilevel antenna structure may be used in many antenna configurations, such as dipoles, monopoles, patch or microstrip antennae, coplanar antennae, reflector antennae, wound antennae, antenna arrays, or other antenna configurations. In addition, multilevel antenna structures may be formed using many manufacturing techniques, such as printing on a dielectric substrate by photolithography (printed circuit technique); dieing on metal plate, repulsion on dielectric, or others.

Other embodiments

The SMD component, including a conducting trace defining an antenna element allows for the mounting of an antenna with standard mass production methods. This is to a large amount possible only due to the miniaturization of the antenna due to the complex geometry of the trace which may be a space-filling curve, a grid-dimension curve, a box counting curve or a contour-curve or the curve having the shape of a multilevel structure.

An IC-package is a device comprising an integrated circuit. Usually the integrated circuit may be enclosed by a protective material such as plastic. Contact means such as pins are accessible from the outside of the package in order to contact the integrated circuit. The IC-package here includes an antenna with a conducting trace which has a complex geometry. The conducting trace or parts thereof may also be connected to the contact means accessible from the outside of the package. The conducting trace or parts thereof may also be connected to the integrated circuit. The integrated circuit may be provided for feeding the antenna. It may also be provided for performing data processing in transmission or reception.

The conducting trace may also be connected at certain points to ground of the IC-package such that certain antenna resonance modes are suppressed or supported.

The integrated circuit may be provided with a metal frame. Such frames may be used for guiding the cutting process of the substrate of the IC-package. The frame preferably has gaps which reduce currents flowing on the frame.

The wireless device has one or more of the above-mentioned antennae and/or one or more of the above-mentioned SMD components and/or one or more of the above mentioned IC-packages.

The antenna or the antenna element of the SMD or the antenna of the IC-package can be contacted in different ways. It is possible to contact only one feeding point so that by appropriate selection of the feeding point, the desired resonant frequency or any other desired antenna characteristic is given.

In a preferred embodiment, two or three or more feeding points/access ports/feeding purposes points are electrically contacted to other electric circuits of the wireless device such that the used feeding point can be selected after the production of the wireless device by an, e.g. electrical switch. This switch may be mechanically operated or electrically operated, such as a transistor or a combination of transistors or the like. The antenna may be connected to an integrated circuit (e.g. the one of the IC-package or any other integrated circuit of the wireless device) which feeds the antenna and/or which connects separated parts of the antenna.

With two, three or more feeding points/access ports electrically contacted, it is also possible not only to use a single feeding point, but also to provide energy to the antenna at two, three or more feeding points at the same time. By using different amounts of energy provided to the different feeding points, antenna characteristics such as resonant frequency, impedance, bandwidth and efficiency may be adjusted continuously.

By selecting a specific contacting mode, the antenna may be operated at resonance at different operating frequencies. This allows for adaptation of the wireless device to different wireless communication systems. Also by connecting one or more feeding points to ground of the wireless device it is possible to select certain antenna properties.

In a preferred embodiment, for at least a part of the antenna and/or the SMD component and/or the IC-package a space is provided between the antenna and/or the SMD component and/or the IC-package to any other member or constructive element of the wireless device, such that the electrical characteristics of the antenna and/or antenna element and/or IC-package can be maintained after mounting the antenna and/or the SMD component and/or IC-package. A space is in particular useful if the conducting trace is provided on one side of a substrate or circuit board and this side of the substrate faces a circuit board to which

substrate or circuit board is mounted. The conducting trace is then protected by the space from mechanical impact by the circuit board due to e.g. scratching. The other side of the antenna or the SMD component may be in contact to other parts of the wireless device.

Even if the antenna and/or the SMD component and/or the IC-package allow for different operating frequencies, it may be in a preferred embodiment desirable to have two, three or more antennae or SMD components with an antenna element or IC-packages. Thereby, it is possible to provide even more operating frequencies to the wireless device. Further it is possible to operate the wireless device simultaneously at two, three or more different operating frequencies using the two, three or more different antennae and/or antenna elements. Also this is interesting for a wireless device featuring diversity and/or multiple input multiple output (MIMO) functionalities. Here at least some of the antennae have the same resonant frequency.

In order to physically hold the antenna or the SMD component or IC-package within the wireless device, it may be possible to use the feeding points, which are not electrically contacted. This may be done, e.g., by soldering the feeding (purposes) point or the access port to a circuit board, where, however, the metallic part of the circuit board has no further electrical connections such that the feeding point is not used to feed energy to the conducting trace or to ground the conducting trace.

The conducting trace is provided in the wireless device, such that a ground plane of the wireless device does not cover the antenna. This allows for a good emission of the radiation by the antenna.

The method allows for selection of the desired antenna property (e.g. the desired resonant frequency) by selecting the appropriate feeding point.

Preferred embodiments of the invention are disclosed in the figures. It is shown in:

Fig. 1 examples of how to calculate the box counting dimension, and examples 1501 through 1514 of space filling curves for antenna design (Fig. 1 b);

Fig. 7 a shows a schematic example of an antenna 14. The antenna 14 has three feeding points 16a, 16b, 16c which here have as an example only, the shape of a square and may be used as solder pads. Between feeding point 16a and 16b, only schematically the connection of the two feeding points is indicated by the dotted line 15a. Here the dotted line 15a is shown as a straight line and is supposed to be substituted by a complex curve such as a space-filling curve, a grid-dimension curve, a box-counting curve, a contour-curve or curve having the shape of a multilevel structure. Equally, the connection between feeding point 16b and 16c is shown schematically only by the dotted line 15b which may be

appropriately substituted by a more complex curve such as a space-filling curve, a grid-dimension curve, a box counting curve, a contour-curve or a curve having the shape of a multilevel structure. In Fig. 7 a, in one of the feeding points 16b, the two portions 15a and 15b are both connected to that feeding point 16b. The other feeding points 16a and 16c are provided at the end of the conducting trace 15. It is also possible to have the conducting trace 15 in such a way that at one end or at two or three or more ends of the conducting trace 15 no feeding point is provided. This may be achieved by omitting the feeding point 16a or 16c or by, e.g., moving the feeding point 16a or 16c towards the feeding point 16b along the conducting trace. The three feeding points 16a, 16b and 16c do not necessarily have to be aligned as shown in Fig. 7 a.

A possible configuration of the antenna 14 is also given by the configuration shown in Fig. 7 a, where the feeding point 16a and the trace portion 15a are omitted.

Another connection mode of the three feeding points 16a, 16b, 16c is shown in Fig. 7 b. The three feeding points 16a, 16b and 16c are connected in a Y-branch style. The dotted lines here have to be considered as being substituted by complex curves such as a space-filling curve, a grid-dimension curve, a box-counting curve, a contour-curve or a curve having the shape of a multilevel structure. If the connection between feeding point 16a and 16b is regarded as one radiating arm the connection between feeding point 16c and the radiating arm is a second radiating arm.

More radiating arms and/or more feeding points may be added to the connection modes shown in Fig. 7 a or 7 b.

In Fig. 7 c a general case of an antenna with separated parts of blocks (15a, 15b, 15c, 15d) is shown. Each separated part has at least one contact means (16a, 16b, 16c, 16d, 16e, 16f). Some separated parts have two or only one contact means. Also three or more contact means are possible for one separated part (not shown). The different parts may be connected together in order to construct a desired antenna configuration. The three parts 15a, 15b, 15c, may be connected one after the other so that a long antenna is achieved. Also a Y-branch configuration is possible e. g. by connecting contact means 16d, 16 e and 16f together. Some parts may not be connected at all. Then the antenna is shorter. Also only one separated part e.g. 15a or 15b may be used. They provide for different resonant frequencies. In summary any possible connection or not-connection of the different

separated parts is possible. In Fig. 7 c the dotted parts are to be considered as representatives of curves with a complex geometry.

Figure 8 illustrates an example tunable antenna 21 having multiple feeding points. The example antenna of Figure 8 includes a conducting trace 20 attached to a dielectric substrate 22. The conducting trace 20 may, for example, be made of copper, aluminum, brass, silver, gold, or some other type of good conducting alloy. The substrate 22 may, for example, be a PCB material, such as plastic, epoxy, FR4, glass fiber, ceramic (LTCC, HTCC), glass, semiconductor, or other materials. The conducting trace 20 may be fabricated on one or more layers of the dielectric substrate 22 using standard PCB manufacturing processes, such as thick film processes (printing, etching) or thin film processes.

The conducting trace 20 defines at least one curve with two ends. One of the ends of the conducting trace 20 may include a connection or feeding port, as illustrated in Figure 8. In addition, the conducting trace 20 includes one or a plurality of feeding points or ports at one, two or more points along the trace. The feeding points may, for example, be formed using soldering pads, solder balls, solder pins, wire-bonds coupled to other input/output pins of the PCB package, or some other means for connecting to the conducting trace. The operating characteristics of the antenna are dependent upon which of the feeding points is used to feed the antenna. Thus, each of the feeding points may be accessed, such that a user may chose the feeding point that best tunes the characteristics of the antenna to suit the device in which the antenna will be mounted. For example, different feeding points may be selected in order to tune the impedance, bandwidth, efficiency and resonant frequency of the antenna.

For miniaturization purposes, at least a portion of the curve defining the conducting trace may be shaped as a space-filling curve, a box-counting, or grid-dimension curve, or a fractal based curve or as a contour-curve or have the shape of a multilevel structure. The conducting trace may include a single radiating arm, or may branch-out in two or more radiating arms. The conducting trace may also be coupled, either through direct contact or electromagnetic coupling, to a conducting polygonal or multilevel surface.

Referring again to Figure 8, the antenna geometry includes different pads along its path, and each pad can be used as a feeding point. Depending on the chosen feeding pad, the electrical antenna length changes. For instance, if the antenna is fed at pad 17, then the

resonating path of the antenna is smaller than if the antenna is fed at pad 18. Thus, the antenna may be tuned to a higher resonant frequency by selecting pad 17 as the antenna feeding point.

In one example, the pads connected along the path of the antenna which are not used to feed the antenna may be used as attachment pads.

In the example of Figure 8, the antenna is a monopole antenna and its geometry is a space-filling shape. In another example, the same antenna structure could be used as a dipole element.

In Figure 8 a pad is provided which has no contact to any other pad or the conducting trace. This pad may be used as an attachment pad, by e.g. soldering it to a circuit board. This use as an attachment pad has no electrical effect and allows only for a mechanical holding of the substrate 22 to the circuit board.

Figure 9 illustrates an example in which the antenna is a discrete component 21 mounted on a PCB. The antenna may be manufactured to be a discrete component using, for instance, a dielectric substrate material. Three different feeding configurations of the antenna are depicted in the example of Figure 9. In the example of Figure 9, the antenna geometry is not visible because the antenna geometry is etched on the other side of the dielectric component.

Example characteristics of an antenna mounted as shown in Figure 9 are illustrated in Figure 10. Figure 10 shows graphs of three curves. The long dashed curve corresponds to the antenna fed at point 18, the continuous curve with the feeding at point 17, and the short dashed curve using the feeding point 19. As illustrated, the resonance can be tuned by choosing the feeding point. This behavior is completely different from e.g. a linear monopole antenna, where the resonant frequency does not depend on the end at which the monopole is contacted. Here, however, the resonant frequency is different for contacting the trace 20 at the end pad 18 or at the end pad 22. This behavior can be found in a similar way for the other claimed and mentioned curve geometries or shapes.

While in Fig. 9, on the right-hand side only the case of contacting one of the possible feeding points is shown, it is also possible to have two or three of the feeding points contacted at the same time.

Figure 11 shows an example of a wireless light switch that incorporates a tunable antenna as described herein. It should be understood, that other wireless light switch designs could also be used, such as differently-shaped light switches. The ground plane of the example switch may be totally or partially filled, depending on the switch configuration.

Figure 12 shows an example return loss and efficiency of a tunable antenna with multiple feeding points mounted on the totally filled ground plane of Figure 11. In this example, only one feed point (pad no.18) is considered. As can be seen the electric antenna properties are different from those of Fig. 10 due to the different environments of the antennae. The antennae themselves of the measurements of Fig. 10 or 12 are similar. With the different feeding points such frequency shifts, efficiency changes, impedance changes or bandwidth changes can be at least partially compensated.

One possible application of the multi-feed antenna is an antenna for GPS systems. Depending on the chosen antenna feeding point it can either cover the 1.575 GHz band or the 1.227GHz frequency band.

Some additional example applications for a tunable antenna having multiple feeding points are illustrated in Figures 13 and 14. The car kit refers e.g. to a part which may be placed inside or onto a holding device which can be stuck to the inside of a windscreen to hold a mirror. The car kit may also be placed e.g. inside a head rest in order to receive audio data for a loudspeaker. In the car kit part an antenna for GPS, radio, mobile communication or other any other wireless communication system may be placed. The Figure shows the circuit board of an example car kit.

Example Methods for Manufacturing Tunable Antenna Component

Following is a description of several possible methods and processes for manufacturing a tunable antenna component with multiple feeding points, as described herein.

In one example, the antenna can be manufactured to be a SMT or SMD component. In this case, the antenna may be etched on a dielectric substrate, such as FR4, Neltek, Rogers or an equivalent material.

In other examples, ceramic, deposited materials and LCP could also be used. Different package manufacturing technologies, such as thin film and thick-film, can be used. A variety of package architectures are also possible, such as DIP, QFP, PGA, BGA, CSP or others.

The following example data is related to the mechanical aspects for manufacturing of the antenna product as a SMT or SMD component.

An example of an antenna is shown in Fig. 15. On the left hand side the top side is shown and on the right hand side the bottom side is shown. Three square shaped feeding points or access ports are shown in three corners of the square shaped antenna (see Fig. 15, right).

-- Example Specifications for Dielectric

Material	Neltec NH9338ST0813RHRH
ϵ_r	3.38 \pm 0 .04
Tan loss	0.00025

-- Example Specifications for Metal Laminate:

Material	Copper foil, 15 μ m, 17 μ m, 20 μ m or 25 μ m.
	Tined Pads

-- Example Specifications for cover lay:

Top	Blue silkscreen ink cover, 25 μ m, 30 μ m or 40 μ m. White silkscreen ink "logo", 25 μ m, 30 μ m or 40 μ m.
Bottom	Black silkscreen ink cover, 50 μ m to 100 μ m. White silkscreen ink "xyz" 25 μ m, 30 μ m or 40 μ m.

-- Example Specifications for INK

Blue (pantone 312)	Blue CARAPACE EMP 110-3245
Black	Black Taiyo PSR4000

The exploded view of the layers of an antenna is shown in Fig. 16. In the middle a 0.8mm Neltec substrate is shown on which a 17 μm thick copper layer is provided from which the antenna and the pads are fabricated. In other examples a 1.0 mm thick substrate is used. The thickness of the copper layer may be varied between 15 to 30 μm . On top of the substrate two ink layers are provided. Below the copper layer two ink layers are provided which provide for different effects. Firstly they give an optical appearance to the device. Secondly they electrically insulate the copper layer and lastly they provide a mask which allows electrical access to the feeding points (here pads). The ink mask is in particular useful for soldering the antenna, since it defines the area where the solder shall or may contact the antenna.

- Example Assembly process:

As a SMT or SMD component, an example assembly process flow is as follows. First, a solder paste may be applied to the mounting pads on the printed wiring board and the devices are placed thereon, and then soldered. When simultaneous reflow for double-sided surface mounting or flow soldering is performed, a temporary adhesive may be used to affix the devices to the printed wiring board before the soldering is performed. A cleaning process may be performed to remove the residual flux, etc., after the soldering process is performed, after which an inspection may be performed. A baking process may be performed before soldering when a moisture-removal treatment is required when a plastic package is used

Figure 17 shows an example where an antenna is mounted on a circuit board (PCB). A space of 0.1 mm is provided between the antenna and the PCB. At the area of the feeding points or access ports solder is provided to electrically bridge the space between the PCB and the antenna to electrically contact the antenna. Where there is no solder the space is empty. The space may also be less or more than 0.01, 0.05, 0.2, 0.5 or 1.0 mm.

- EXAMPLE ENVIRONMENTAL INTEGRITY TEST

The example antenna maintains all the dimensions and electric characteristic in the range that tests IEC 68-2-56 (humidity) and IEC 68-2-1.2 (temperature) operate.

- PACKING EXAMPLE

The antennas may, for example, be delivered in tape and reel. Fig. 18 shows an example of a tape and reel packaging.

Figure 19 illustrates an example IC package having an integrated antenna. Also shown on the example IC package are a semiconductor die or chip (IC chip) and a plurality of bonding pads. The antenna is illustrated in the top region of the package, the IC chip in the lower left corner and the bonding pads distributed over the IC-package.

The antenna is formed from a conducting trace attached to a surface of the IC package. The antenna may, for example, be attached to the dielectric or semiconductor substrate of the package. The conducting trace may, for example, be made of copper, aluminum, brass, silver, gold or some other good conducting alloy. The substrate material to which the antenna is attached may, for example, be a PCB material, such as a low cost material based on plastic, epoxy, FR4, fiber glass or laminate materials or a more sophisticated material such as ceramic (LTCC, HTCC), glass, or semiconductor materials. The conductive trace may, for example, be fabricated on at least one of the layers of the substrate by a standard manufacturing process, such as thick film processes (printing, etching) or thin film processes.

The antenna includes a plurality of possible feed points (see feeding points # 1 – # 5 in Fig. 19) along the conducting trace at which the antenna may be accessed, each of which may be configured as the feed point of the antenna by connecting the feed point to a bonding pad. The bonding pad couples the antenna feed point to the IC chip. The connection between the antenna feed point and the IC chip may, for example, be through an external or internal PCB trace, through an external bypass, and/or through a circuit including other electrical and/or RF components. It should be understood that the bonding pads may be metallic pads, solder balls, solder pins, wire-bond connections, or other input/output devices for an IC package.

The conductive trace of the antenna defines one or more curves (the term curve as used herein may include curved and/or straight segments.) In some examples, for miniaturization purposes, at least a portion of the curve(s) defining the conducting trace may define a space-filling curve, a box-counting curve, a grid-dimension curve, a fractal based curve and/or a contour curve, or have the shape of a multilevel structure, as described above. In some examples, the conductive trace may define a single curve, while in other examples it may define two or more curves, each of which may include a space-filling curve, box-counting curve, grid-dimension curve, a fractal based curve and/or a contour curve or have the shape of a multilevel structure. Additionally, in some examples a portion of the curve(s)

may be coupled either through direct contact or electromagnetic coupling to a multilevel structure, as described above.

The IC package may provide access to the multiple feed points of the antenna from outside of the package. In this manner, the end-user can choose the proper port for feeding the antenna and/or define the connectivity among the other ports to optimally tune the antenna in terms of resonance frequency and impedance, for example to a wireless device in which the IC package is mounted. By providing user access to the multiple feed points, a single package layout can be standardized and used in a wide range of applications, for example in different devices with different form factors (such as laptops, PDAs, MP3 players, handsets, GPS navigators, multimedia terminals, etc.), and in different geographical domains with different spectrum allocations for wireless terminals.

Also it may be possible that no direct access to the feed points is given from the outside. In this case the antenna is connected to the chip which feeds and controls the antenna. The antenna is therefore contacted indirectly from the outside through the chip.

In some arrangements, one or more of the several ports at which the antenna can be accessed through pads of the package may be used as short-circuit points for the antenna, that is points that are connected to an internal ground plane of the package or to the external ground plane on the PCB of the device in which the IC package is mounted. Thus, the same antenna geometry can be arranged for instance as a monopole antenna or as an inverted-F antenna (IFA/PIFA). The IFA configuration of the antenna can be advantageous for some types of ground planes on which the antenna impedance is capacitive.

The configurability of the antenna may provide the end-user with extra degrees of freedom to adjust for instance the resonance frequency, input impedance, bandwidth, gain, efficiency and radiation pattern of the antenna to an even wider variety of application environments with PCBs of many different sizes, shapes and clearances.

In some examples, the antenna geometry may include several separated parts, or blocks, not necessarily equal, each one containing at least one point that can be accessed from the outside of the package, for instance through a pad, or from the chip. Depending on the PCB on which the AiP (Antenna in Package) module is mounted, the antenna feeding point, the connections between different parts of the antenna, and whether these parts are connected to ground or not can be selected to optimize the resonance frequency, the input impedance

and/or the bandwidth of the antenna. In some examples, antenna geometries may also include parasitic elements.

The assembly of a die or chip to the substrate of a FWSiP/FWSoC module may result in the substrate becoming warped. This problem can be of especially concern in Multi-Chip Modules (MCMs). When reflowing a chip onto a package substrate, the cycle of heating and subsequent cooling of the surfaces that come together upon assembly may develop stresses on the substrate due to the differences between the thermal expansion coefficient of the material of the substrate and that of the chip. If the substrate is not rigid enough, it will become warped compromising the planarity, and hence the solderability, of the resulting FWSiP/FWSoC module.

The warpage effect is more typically severe in thin substrates, particularly when the chip is positioned in a corner of the substrate to leave room for the antenna. Reinforcement of the substrate may be necessary to avoid this problem. This can be achieved by placing an extra layer of dielectric material on top of the antenna. The detuning of the resonance frequency of the antenna can be corrected by selecting the appropriate feeding pad.

In some examples, the geometry of the antenna may be such that it is convenient to substantially arrange the die or chip at the center of the substrate and reserve the outer perimeter region of the substrate for the footprint of the antenna. Such an arrangement may minimize the warpage of the substrate for a given thickness, as the stresses produced by the assembly of the chip are more uniformly distributed.

Some semiconductor and/or package fabrication technologies use a frame to delimitate the area of the die or the substrate. Such a frame is typically used as a reference when cutting a semiconductor wafer or a laminate substrate panel with high degree of accuracy. This frame is often made of lossy metals (for instance tantalum), which can compromise the frequency tuning, bandwidth and/or radiation performance of the antenna integrated in the package, as the currents induced on the conductive frame may tend to cancel those of the antenna. This problem may be reduced or eliminated by including gaps along the perimeter of the frame, because the presence of discontinuities on the frame makes it difficult for currents to be induced, while still providing guidance for the cutting process.

Figure 20 shows an example of an IC package having a miniature antenna and an IC chip integrated on a PCB. The antenna in this example (illustrated in the upper right corner of the

PCB) includes a portion that is shaped as a space-filling curve and a portion that extends from the space-filling curve portion to a feed point. Other feed points may be provided here to which the antenna extends with a certain portion. The IC chip is illustrated in the lower left corner of the IC package. The PCB substrate is partially covered by a ground plane (illustrated as the major part on the PCB). The exposed portion of the PCB substrate (i.e., the portion that is not covered by the ground plane) is also shown and located in the upper right corner of the PCB close to the IC-package. The border between the part of the PCB that is covered by the ground plane and the part not covered by the ground plane is indicated by a dashed line. The PCB may, for example, be a 1mm thick PCB for a wireless device, in which a substantial portion of the PCB substrate is covered by a ground plane.

The IC package is attached to the PCB substrate such that the antenna footprint is included entirely within the exposed portion of the PCB substrate, with the tip of the antenna positioned at the upper right corner of the PCB substrate in order to provide as much clearance as possible between the tip of the antenna and the PCB ground plane. Positioning the IC package at the corner of the PCB substrate enables the tip of the antenna to be positioned away from the PCB ground plane, while minimizing the amount of exposed PCB substrate. That is, the IC package position allows a maximum amount of the PCB substrate to be covered by the ground plane, while still achieving the improved antenna performance resulting from positioning the tip of the antenna at a distance away from the PCB ground plane.

Figure 21 shows another example of an IC package that integrates a miniature antenna and an IC chip on the same substrate. This example is similar to the example of Figure 20, using the example antenna shown in Figure 19. As described above, this example antenna includes multiple feed points, each of which may be configured as the feed point for the antenna. The electrical length of the antenna differs depending on the chosen feeding point. For instance, if the antenna of Figure 19 is fed at feeding point 2, then the resonating path of the antenna is smaller than if the antenna is fed at feeding point 1. This permits a higher resonance frequency if the antenna is fed at feeding point 2. Figure 21 shows an advantageous placement of the IC package of Figure 19 on a PCB with a substantial area of the PCB covered by a ground plane.

In the example of Figure 21, the bonding pads connected at the feeding points along the path of the antenna which are not used to feed the antenna act simply as fixation pads to provide mechanical stability to the package. The example antenna illustrated in Figure 21 is

a monopole and its geometry is a space-filling shape. The same antenna can be used as a dipole element.

Figure 22 illustrates example performance characteristics of the antenna of Figure 21. Figure 22 includes two graphs, each graph containing five curves corresponding to the five feed points of the antenna. Figure 22 illustrates how the resonance can be tuned by choosing the feeding point from the lowest resonance frequency (at feed point 1) to the highest (at feed point 5).

Figure 23 illustrates the same IC package as shown in Figure 22 attached to a PCB having a differently shaped ground plane. The border of the ground plane on the PCB is again indicated by a dashed line. This example illustrates the adaptability of the antenna integrated in the IC package. In this particular example, it may be advantageous to configure the antenna as an inverted F antenna (IFA) by selecting the proper points for feeding and grounding.

In other examples, the miniature antenna may include several pads for feeding and/or grounding along the antenna path. In order to achieve the desired performance, the antenna could be grounded at more than one of the pads connected along to its path.

Figure 24 compares the typical performance of the antenna when mounted on a PCB with a ground plane as depicted in Figure 23, when configured as monopole (feeding at point 4) and as IFA (feeding at point 3 and grounding at point 1). It is observed that the IFA configuration is better matched to the particularities of this ground plane.

The arrangement of the antenna inside the IC package in the example of Figure 20 makes it advantageous to mount the IC package on the upper right corner of the PCB, such that the tip of the antenna is at a maximum distance from the ground plane. However, if the package illustrated in Figure 20 were mounted on the upper left corner of the PCB such that the tip of the antenna was closest to the ground plane, then the antenna may exhibit decreased performance unless the ground plane clearance is increased. Figure 25 illustrates an example antenna with two feeding points. Depending on the placement of the package on the PCB, one feed point or the other can be selected in order to achieve a maximum possible distance between the tip of the antenna and the ground plane. The symmetry of the geometry and the flexibility of the design of the antenna makes the resulting FWSoc/FWSiP more versatile.

Figure 26 illustrates an example IC package that includes a plurality of separate antenna geometries (antenna parts or blocks). The antenna blocks may each have different sizes and geometries, including space-filling curves, grid dimension curves, box counting curves and/or contour curves or have the shape of a multilevel structure. In other examples, two or more of the antenna blocks may have the same antenna geometry and/or size. The antenna blocks include at least one feed point that can be accessed from the outside of the package through a pad or is connected to a chip. The interconnections between different blocks of the antenna can be defined to optimize the antenna parameters for a particular ground plane. In the same way, the optimal feeding point can be selected among the different available pads.

In one example, the interconnection between two or more of the antenna blocks of Figure 26 may include a reactive element, either capacitive or inductive. In another example, the antenna resulting from the interconnection of two or more of the antenna blocks of Figure 26 may be grounded by at least one pad connected to one block that constitutes the antenna. In another example, one or more of the antenna blocks in Figure 26 may be used to create a parasitic element electromagnetically coupled with the set of blocks that form the main antenna element connected to the feeding point.

Figure 27 illustrates an example IC package in which the chip or die is located at the center of the PCB substrate and the antenna footprint is located in the outside perimeter of the package. The antenna path forms a loop with different pads along its path available to be used as feed points. Schematically two wire bonds are shown which connect the integrated circuit with two feeding points of the loop. Also more wire bonds that connect the chip with the conducting trace may be provided. It may also be possible to connect all feeding points of the conducting trace with the integrated circuit and to remove some of the connections later in order to select the desired connections.

Figure 28 a shows an IC package substrate that contains an antenna and a metal frame on its perimeter that is used as a reference to cut a single IC substrate out of a panel. Figures 28 b and 28 c show the same IC package substrate in which one gap and three gaps, respectively, have been created on each side of the square metal frame.

Figure 29 illustrates the improved antenna performance created by including gaps in the metal frame, as illustrated in Figures 28 b and 28 c. The typical performance of the antenna

is illustrated in Figure 29, showing the antenna performance with no frame (continuous line), with a frame having no gaps (short dashed line), with a frame having one (1) gap (dashed dotted line) and with a frame having three (3) gaps (long dashed line.) The results show that the performance that the antenna exhibited in a package without metal frame may be substantially restored by introducing the gaps in the metal frame.

Example Applications

The flexible design of the antenna, and its careful integration in the IC package, and on the PCB, make it possible to use this FWSiP solution in a wide set of wireless connectivity applications. Some example target market segments where it can be used include: Bluetooth™ enabled handsets, Mini-PCI (Notebook PC with Wi-Fi module integrated), Compact flash wireless cards, Wireless USB/UART dongles, PCMCIA wireless cards, Headsets, Pocket PC with integrated Wi-Fi, Access points for hot-spots, Wireless switches, or Wireless sensors.

Figure 30 shows an example of a Bluetooth™ enabled handset that uses a FWSiP solution. The device is mounted in the lower right corner of the handset. The area requirements on the handset (Bluetooth™ chipset + antenna + clearance) of a FWSiP solution could represent substantial area savings over the conventional solution.

Figure 31 shows an example return loss and efficiency of the FWSiP solution for Bluetooth™ when mounted on the PCB of a handset as in Figure 30.

Figure 32 shows another example placement of the Bluetooth™ FWSiP solution on the PCB of a handset. The position of the FWSiP module is chosen to achieve good antenna performance while minimizing the PCB space requirements.

Figure 33 illustrate example applications of an IC package including a miniature antenna as described herein. Figure 33 a shows a USB dongle for Bluetooth™, and Figure 33 b illustrates a wireless light switch using the ZigBee standard. In Fig. 33 b upper part the outer appearance of the light switch is shown, while in Fig. 33 b, lower part the ground plane with the FWSiP module is shown.

While the invention has been described with respect to specific examples including presently preferred modes of carrying out the invention, those skilled in the art will appreciate that there are numerous variations and permutations of the above described systems and

techniques that fall within the spirit and scope of the invention as set forth in the appended claims.

Claims

1. An antenna comprising:

a conducting trace (15, 20), said conducting trace (15, 20) defining a curve (1, 4, 5, 6, 6', 6'', 8), said curve (1, 4, 5, 6, 6', 6'', 8) including two or more feeding points (16a, 16b, 16c, 17, 18, 19), a portion of said curve (1, 4, 5, 6, 6', 6'', 8) being shaped according a geometry selected from a group of geometries including a space-filling curve, a grid-dimension curve, a box-counting curve and a contour curve or said curve (1, 4, 5, 6, 6', 6'', 8) or a portion of said curve (1, 4, 5, 6, 6', 6'', 8) having the shape of a multilevel structure.

2. The antenna according to claim 1, **characterized in** that at each or at least one or two or three or more feeding points (16a, 16b, 16c, 17, 18, 19) a means for electrically contacting said conducting trace (15, 20) is provided wherein at least one or all of said means for contacting is preferably selected from a group including a soldering pad, a solder ball, a solder pin, a wire-bond and a contact pin.

3. The antenna according to any of claims 1 or 2, **characterized in** that said conducting trace (15, 20) comprises a rigid piece.

4. The antenna according to any of claims 1 to 3, **characterized in** that said conducting trace (15, 20) comprises at least one material selected from the group of materials including metal, iron, steel, stainless steel, copper, aluminum, brass, silver, gold, alloy and conducting polymer.

5. The antenna according to any of claims 1 to 4, **characterized in** that said conducting trace (15, 20) is hold by a rigid backing (22).

6. The antenna according to claim 5, **characterized in** that said rigid backing (22) comprises at least one material selected from the group of materials including a dielectric substrate, a PCB material, plastic, epoxy, FR4, Neltek, Rogers, deposited materials, LCP, glass fiber, ceramic, glass, insulator, and semiconductor.

7. The antenna according to any of claims 1 to 6, **characterized in** that said antenna is provided in at least one way selected from the group of ways including said antenna is provided directly on a circuit board (22),

said antenna is printed directly on a circuit board (22),
said antenna is etched from a conducting layer of a circuit board (22),
said antenna is provided on one or more layers of a multilayer circuit board,
said antenna is provided on at least an internal layer of a multilayer circuit board,
said antenna is provided on at least an external layer of a multilayer circuit board,
said antenna is prepared by a thick film process, and
said antenna is prepared by a thin film process.

8. The antenna according to any of claims 1 to 7, **characterized in** that said conducting trace (15, 20) has one, two, three or more radiating arms.

9. The antenna according to any of claims 1 to 8, **characterized in** that said conducting trace (15, 20) is continuous or discontinuous, wherein two, three or more parts of said conducting trace (15, 20) at the discontinuity are electromagnetically coupled to each other.

10. The antenna according to any of claims 1 to 9, **characterized in** that said conducting trace (15, 20) comprises two, three, four or more separated parts, that can be contacted each at one, two, three or more feeding points (16a, 16b, 16c, 17, 18, 19) and which parts can be contacted individually and/or can be connected together e.g. by an external or internal connection which may include one or more of the group comprising a bypass, a circuit, a switch, a transistor, a filter, a matching network, an inductive device, a capacitive device, a passive network, and an active network.

11. The antenna according to any of claims 1 to 10, **characterized in** that said conducting trace (15, 20) is coupled to another antenna structure such as e.g. a polygonal or multilevel surface wherein the coupling may be achieved by electromagnetic coupling or by direct contact.

12. The antenna according to any of claims 1 to 11, **characterized in** that said conducting trace (15, 20) or at least part of said conducting trace (15, 20) is covered by an insulator.

13. The antenna according to claim 12, **characterized in** that said insulator is at least one selected from the group including ink, foil, paper, paint, plastic, a dielectric substrate, a PCB material, epoxy, FR4, Neltek, Rogers, deposited materials, LCP, glass fiber, ceramic, glass, and semiconductor.

14. The antenna according to any of claims 1 to 13, **characterized in** that said conducting trace (15, 20) is uncovered at said feeding points (16a, 16b, 16c, 17, 18, 19) or that said feeding points (16a, 16b, 16c, 17, 18, 19) are covered by an easy removable cover.

15. The antenna according to any of claims 1 to 14, **characterized in** that said antenna is at least one antenna selected from a group of antennae including a monopole, a dipole, a patch antenna, a slot antenna, a microstrip antenna, a coplanar antenna, a wound antenna, an aperture antenna, a loop antenna, an inverted F-antenna and an antenna array.

16. The antenna according to any of claims 1 to 15, **characterized in** that said conducting trace (15, 20) is provided on a circuit board together with an integrated circuit.

17. The antenna according to claim 16, **characterized in** that said integrated circuit is connected to said conducting trace (15, 20) by at least one of the group of an external connection, an internal connection, a circuit board trace, an electrical circuit, a capacitive device, an inductive device, a switch, a transistor, a wire bond, and a resistor.

18. The antenna according to any of claims 16 or 17, **characterized in** that said integrated circuit is provided in relation to said conducting trace (15, 20) in at least one way of the group of ways including
said conducting trace (15, 20) is not covered by said integrated circuit,
said conducting trace (15, 20) is partially covered by said integrated circuit,
said conducting trace (15, 20) is partially covered at least at one, two, three or more of said feeding points (16a, 16b, 16c, 17, 18, 19) by said integrated circuit,
said conducting trace (15, 20) is entirely covered by said integrated circuit,
at least one, two, three or more or all of said feeding points (16a, 16b, 16c, 17, 18, 19) are covered by said integrated circuit,
said conducting trace (15, 20) surrounds said integrated circuit, and
said conducting trace (15, 20) is on one, two or three sides next to said integrated circuit.

19. The antenna according to any of claims 1 to 18, **characterized in** that said conducting trace (15, 20) is contacted at two or more feeding points (16a, 16b, 16c, 17, 18, 19) by removable connections.

20. The antenna according to any of claims 1 to 19, **characterized in** that the maximum extension of said conducting trace (15, 20) is less than $1/5$, $1/7$, $1/10$, $1/15$ or $1/20$ of the free space wavelength of the resonant frequency.

21. An SMD component (21) including two or more access ports (16a, 16b, 16c, 17, 18, 19), said access ports (16a, 16b, 16c, 17, 18, 19) being connected to two or more points of a conducting trace (15, 20), said conducting trace (15, 20) defining a curve (1, 4, 5, 6, 6', 6'', 8), said curve (1, 4, 5, 6, 6', 6'', 8) including a space-filling geometry, a grid-dimension geometry, a box-counting geometry or a contour curve geometry or said curve (1, 4, 5, 6, 6', 6'', 8) or a portion of said curve (1, 4, 5, 6, 6', 6'', 8) having the shape of a multilevel structure, said conducting trace (15, 20) defining an antenna element within said SMD component (21).

22. An SMD component (21) including two or more access ports (16a, 16b, 16c, 17, 18, 19), said access ports (16a, 16b, 16c, 17, 18, 19) being connected to two or more points of a conducting trace (15, 20), said conducting trace (15, 20) defining a curve (1, 4, 5, 6, 6', 6'', 8), at least a portion of said curve (1, 4, 5, 6, 6', 6'', 8) including a space-filling geometry, a grid-dimension geometry, a box-counting geometry or a contour curve geometry or said curve (1, 4, 5, 6, 6', 6'', 8) or a portion of said curve (1, 4, 5, 6, 6', 6'', 8) having the shape of a multilevel structure, said conducting trace (15, 20) defining an antenna element within said SMD component (21).

23. The SMD component according to claim 21 or 22, **characterized in** that said at least one, two, three or all of said access ports (16a, 16b, 16c, 17, 18, 19) comprise at least one element selected from a group including a soldering pad, a solder ball, a solder pin, a wire-bond and a contact pin.

24. The SMD component according to any of claims 21 to 23, **characterized in** that said conducting trace (15, 20) comprises a rigid piece.

25. The SMD component according to any of claims 21 to 24, **characterized in** that said conducting trace (15, 20) comprises at least one material selected from the group of materials including metal, iron, steel, stainless steel, copper, aluminum, brass, silver, gold, alloy and conducting polymer.

26. The SMD component according to any of claims 21 to 25, **characterized in** that said conducting trace (15, 20) is hold by a rigid backing (22).

27. The SMD component according to claim 26, **characterized in** that said rigid backing (22) comprises at least one material selected from a group of materials including a dielectric substrate, a PCB material, plastic, epoxy, FR4, Neltek, Rogers, deposited materials, LCP, glass fiber, ceramic, glass, insulator, and semiconductor.

28. The SMD component according to any of claims 21 to 27, **characterized in** that said antenna element is provided in at least one way selected from the group of ways including said antenna element is provided directly on a circuit board (22),
said antenna element is printed directly on a circuit board (22),
said antenna element is etched from a conducting layer of a circuit board (22),
said antenna element is provided on one or more layers of a multilayer circuit board,
said antenna element is provided on at least an internal layer of a multilayer circuit board,
said antenna element is provided on at least an external layer of a multilayer circuit board,
said antenna element is prepared by a thick film process, and
said antenna element is prepared by a thin film process.

29. The SMD component according to any of claims 21 to 28, **characterized in** that said conducting trace (15, 20) has one, two, three or more radiating arms.

30. The SMD component according to any of claims 21 to 29, **characterized in** that said conducting trace (15, 20) is continuous or discontinuous, wherein two, three or more parts of said conducting trace (15, 20) at the discontinuity are electromagnetically coupled to each other.

31. The SMD component according to any of claims 21 to 30, **characterized in** that said conducting trace (15, 20) comprises two, three, four or more separated parts, that can be contacted each at one, two, three or more access ports (16a, 16b, 16c, 17, 18, 19) and which parts can be contacted individually and/or can be connected together e.g. by an external or internal connection which may include one or more of the group comprising a bypass, a circuit, a switch, a transistor, a filter, a matching network, an inductive device, a capacitive device, a passive network, and an active network.

32. The SMD component according to any of claims 21 to 31, **characterized in** that said conducting trace (15, 20) is coupled to another antenna structure such as e.g. a polygonal or multilevel surface wherein the coupling may be achieved by electromagnetic coupling or by direct contact.

33. The SMD component according to any of claims 21 to 32, **characterized in** that said conducting trace (15, 20) or at least part of said conducting trace (15, 20) is covered by an insulator.

34. The SMD component according to claim 33, **characterized in** that said insulator is at least one selected from the group including ink, foil, paper, paint, plastic, a dielectric substrate, a PCB material, epoxy, FR4, Neltek, Rogers, deposited materials, LCP, glass fiber, ceramic, glass, and semiconductor.

35. The SMD component according to any of claims 21 to 34, **characterized in** that said access ports (16a, 16b, 16c, 17, 18, 19) are uncovered or that said access ports (16a, 16b, 16c, 17, 18, 19) are covered by an easy removable cover.

36. The SMD component according to any of claims 21 to 35, **characterized in** that said antenna element is comprised by at least one antenna of the group of antennas including a monopole, a dipole, a patch antenna, a slot antenna, a microstrip antenna, a coplanar antenna, a wound antenna, an aperture antenna, a loop antenna, an inverted F antenna, and an antenna array.

37. The SMD component according to any of claims 21 to 36, **characterized in** that said conducting trace (15, 20) is provided on a circuit board together with an integrated circuit.

38. The SMD component according to claim 37, **characterized in** that said integrated circuit is connected to said conducting trace (15, 20) by at least one of the group of an external connection, an internal connection, a circuit board trace, an electrical circuit, a capacitive device, an inductive device, a switch, a transistor, a wire bond, and a resistor.

39. The SMD component according to any of claims 37 or 38, **characterized in** that said integrated circuit is provided in relation to said conducting trace (15, 20) in at least one way of the group of ways including
said conducting trace (15, 20) is not covered by said integrated circuit,

said conducting trace (15, 20) is partially covered by said integrated circuit,
said conducting trace (15, 20) is partially covered at least at one, two, three or more of said access ports (16a, 16b, 16c, 17, 18, 19) by said integrated circuit,
said conducting trace (15, 20) is entirely covered by said integrated circuit,
at least one, two, three or more or all of said access ports (16a, 16b, 16c, 17, 18, 19) are covered by said integrated circuit,
said conducting trace (15, 20) surrounds said integrated circuit, and
said conducting trace (15, 20) is on one, two or three sides next to said integrated circuit.

40. The SMD component according to any of claims 21 to 39, **characterized in** that said conducting trace (15, 20) is contacted at two or more access ports (16a, 16b, 16c, 17, 18, 19) by removable connections.

41. The SMD component according to any of claims 21 to 40, **characterized in** that the maximum extension of said conducting trace (15, 20) is less than $1/5$, $1/7$, $1/10$, $1/15$ or $1/20$ of the free space wavelength of the resonant frequency.

42. An IC package containing an antenna comprising a conducting trace (15, 20), said trace (15, 20) defining a curve (1, 4, 5, 6, 6', 6'', 8), a portion of which being shaped according a geometry selected from a group of geometries including a space-filling curve, a grid-dimension curve, a box-counting curve, and a contour curve or the curve (1, 4, 5, 6, 6', 6'', 8) or a portion of said curve (1, 4, 5, 6, 6', 6'', 8) having the shape of a multilevel structure, said trace (15, 20) including two or more points (16a, 16b, 16c, 17, 18, 19) along its path at which it can be accessed for feeding purposes.

43. The IC package according to claim 42, **characterized by** at least one, two, three or all of said feeding purposes points (16a, 16b, 16c, 17, 18, 19) being accessible from the outside of said IC package through a contact means such as e. g. a pad, a pin or a ball.

44. The IC package according to claim 42 or 43, **characterized in** that at least one, two, three or all of said feeding purposes points (16a, 16b, 16c, 17, 18, 19) are connected to the integrated circuit of said IC package and preferably at least one, two, three or all of those feeding purposes points (16a, 16b, 16c, 17, 18, 19) are not directly accessible from the outside of said IC package.

45. The IC package according to any of claims 42 to 44, **characterized in** that said conducting trace (15, 20) comprises at least one material selected from the group of materials including metal, iron, steel, stainless steel, copper, aluminum, brass, silver, gold, alloy and conducting polymer.

46. The IC package according to any of claims 42 to 45, **characterized in** that, said conducting trace (15, 20) is hold by a rigid backing.

47. The IC package according to claim 46, **characterized in** that said rigid backing (22) comprises at least one material selected from the group of materials including a dielectric substrate, a PCB material, plastic, epoxy, FR4, Neltek, Rogers, deposited materials, LCP, glass fiber, ceramic, glass, insulator, and semiconductor.

48. The IC package according to any of claims 42 to 47, **characterized in** that said conducting trace (15, 20) is provided in at least one way selected from the group of ways including

said conducting trace (15, 20) is provided directly on a circuit board (22),

said conducting trace (15, 20) is printed directly on a circuit board (22),

said conducting trace (15, 20) is etched from a conducting layer of a circuit board (22),

said conducting trace (15, 20) is provided on one or more layers of a multilayer circuit board,

said conducting trace (15, 20) is provided on at least an internal layer of a multilayer circuit board,

said conducting trace (15, 20) is provided on at least an external layer of a multilayer circuit board,

said conducting trace (15, 20) is prepared by a thick film process,

said conducting trace (15, 20) is prepared by a thin film process,

said conducting trace (15, 20) is not covered by the integrated circuit of said IC package,

said conducting trace (15, 20) is partially covered by said integrated circuit,

said conducting trace (15, 20) is partially covered at least at one, two, three or more of said feeding purposes points (16a, 16b, 16c, 17, 18, 19) by said integrated circuit,

said conducting trace (15, 20) is entirely covered by said integrated circuit,

at least one, two, three or more or all of said feeding purposes points (16a, 16b, 16c, 17, 18, 19) are covered by said integrated circuit,

said conducting trace (15, 20) surrounds said integrated circuit, and

said conducting trace (15, 20) is on one, two, or three sides next to said integrated circuit.

49. The IC package according to any of claims 42 to 48, **characterized in** that said conducting trace (15, 20) has one, two, three or more radiating arms.

50. The IC package according to any of claims 42 to 49, **characterized in** that said conducting trace (15, 20) is continuous or discontinuous, wherein two, three or more parts of said conducting trace (15, 20) at the discontinuity are electromagnetically coupled to each other.

51. The IC package according to any of claims 42 to 50, **characterized in** that said conducting trace (15, 20) comprises two, three, four or more separated parts, that can be contacted each at one, two, three or more feeding purposes points (16a, 16b, 16c, 17, 18, 19) and which parts can be contacted individually and/or can be connected together e.g. by an external or internal connection which may include one or more of the group comprising a bypass, a circuit, a switch, a transistor, a filter, a matching network, an inductive device, a capacitive device, a passive network, and an active network.

52. The IC package according to any of claims 42 to 51, **characterized in** that said conducting trace (15, 20) is coupled to another antenna structure such as e.g. a polygonal or multilevel surface wherein the coupling may be achieved by electromagnetic coupling or by direct contact.

53. The IC package according to any of claims 42 to 52, **characterized in** that said conducting trace (15, 20) or at least part of said conducting trace (15, 20) is covered by an insulator.

54. The IC package according to claim 53, **characterized in** that said insulator is at least one selected from the group including ink, foil, paper, paint, plastic, a dielectric substrate, a PCB material, epoxy, FR4, Neltek, Rogers, deposited materials, LCP, glass fiber, ceramic, glass, and semiconductor.

55. The IC package according to any of claims 42 to 54, **characterized in** that said antenna is at least one selected from a group including a monopole, a dipole, a patch antenna, a slot antenna, a microstrip antenna, a coplanar antenna, a wound antenna, an aperture antenna, a loop antenna, an inverted F-antenna and an antenna array.

56. The IC package according to any of claims 42 to 55, **characterized in** that the integrated circuit of said IC package is connected to said conducting trace (15, 20) by at least one of the group of an external connection, an internal connection, a circuit board trace, an electrical circuit, a capacitive device, an inductive device, a switch, a transistor, a wire bond and a resistor.

57. The IC package according to any of claims 42 to 56, **characterized in** that said conducting trace (15, 20) is connected to ground of said IC package at one, two, three or more feeding purposes points (16a, 16b, 16c, 17, 18, 19).

58. The IC package according to any of claims 42 to 57, **characterized in** that the integrated circuit of said IC package is provided in a way selected from the group including
at a corner of said IC package,
at the center of said IC package,
at the side of said IC package between two corners of said IC package.

59. The IC package according to any of claims 42 to 58, **characterized in** that a metal frame of said IC package, provided e.g. for orienting the cutting process of the package substrate, is provided with one, two, three or more gaps preferably at each side of said IC package.

60. The IC package according to any of claims 42 to 59, **characterized in** that the maximum extension of said conducting trace (15, 20) is less than $1/5$, $1/7$, $1/10$, $1/15$ or $1/20$ of the free space wavelength of the resonant frequency.

61. The antenna according to any of claims 1 to 20 or the SMD component according to any of claims 21 to 41 or the IC package according to any of claims 42 to 60, **characterized in** that

said space filling curve is defined by

a curve in which at least a portion of said curve or the entire curve has at least five segments that are connected in such a way that each segment forms an angle with any adjacent segments, such that no pair of adjacent segments define a larger straight segment, wherein said curve or said portion of said curve does not intersect with itself at any point except possibly the initial and final point or by

a non-periodic curve including a number of connected straight or essentially straight segments smaller than a fraction of the operating free-space wave length, where said segments are arranged in such a way that no adjacent and connected segments form another longer straight segment and wherein none of said segments intersect each other

and said grid-dimension curve is defined by

a curve in which at least a portion of said curve or the entire curve has a grid dimension D which is calculated by

$$D = - \frac{\log(N2) - \log(N1)}{\log(L2) - \log(L1)}$$

wherein L1 and L2 are the cell sizes of a first and second grid of cells respectively completely covering said geometry with L2 being smaller than L1 and N1 and N2 are the number of cells including at least a point of said portion of said curve or of said entire curve of said first and second grid respectively and wherein D is larger than a minimum value selected from the group of minimum values including 1.0, 1.1, 1.2, 1.25, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, and 2.9; or by

a curve intersecting at least 50 %, 60%, 70%, 80 % or 90 % of the cells of a grid with at least 25 identical cells enclosing said curve; or by

a curve intersecting at least 1, 2, 3, 4, 5, 7, 10, 13, 15, 20 cells twice within a grid of at least 25 identical cells enclosing said curve;

and said box-counting curve is defined by

a curve in which at least a portion of said curve or the entire curve has a box-counting dimension D which is calculated by

$$D = - \frac{\log(N2) - \log(N1)}{\log(L2) - \log(L1)}$$

wherein L1 and L2 are the sizes of rectangular or substantially squared boxes of a first n x n and a second 2n x 2n grid respectively completely covering said geometry with L2 being smaller than L1 and N1 and N2 are the number of boxes including at least a point of said

portion of said curve or of said entire curve of said first and second grid respectively, and wherein D is larger than a minimum value selected from the group of minimum values including 1.0, 1.1, 1.2, 1.25, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, and 2.9, or by

a curve that intersects at least one point of at least 14, 16, 18, 20, or 22 boxes of a 5 x 5 grid of identical boxes enclosing said curve; or by

a curve that crosses at least 1, 2, 3, 4, 5, 7, 10, 13, 15, 20 boxes twice within a 5 x 5 grid of identical boxes enclosing said curve;

and the contour curve is defined by

a planar curve (4, 5, 6) in which at least a portion of said curve or the entire curve is such that the ratio $Q = C/E$ of the length C of the circumference of said portion of said curve or of said entire curve and of the largest extension E of said portion of said curve or of said entire curve is larger than a minimum value selected from the group of minimum values including 2.1, 2.25, 2.5, 2.75, 3.0, 3.1, 3.2, 3.25, 3.3, 3.5, 3.75, 4.0, 4.5, 5.0, 6, 7, 8, 9, 10, 12, 15, 20, 25, 30, 40, 50, 75, and 100, or by

a three-dimensional curve (8) where for the entire curve or at least a portion of the curve there exists a planar plane (11) such that $Q = C/E$ is larger than a minimum value selected from the group of minimum values including 2.1, 2.25, 2.5, 2.75, 3.0, 3.1, 3.2, 3.25, 3.3, 3.5, 3.75, 4.0, 4.5, 5.0, 6, 7, 8, 9, 10, 12, 15, 20, 25, 30, 40, 50, 75, and 100 with C, the length of the circumference, and E, the largest extension, being determined from the orthogonal projection (10) of said entire curve (8) or of at least said portion of said curve onto said planar plane (11),

and the multilevel structure is defined by

a structure including several elements which are geometrical elements such as polygons or polyhedrons of the same type or of different type which are coupled to each other by direct contact or by electromagnetic coupling due to their proximity wherein the majority of said elements have more than 50% of their perimeter or of their surface not in contact with any other element and preferably at least two of said elements have a different size.

62. A wireless device comprising at least one antenna according to any of claims 1 to 20 or 61.

63. The wireless device according to claim 62, **characterized in** that said at least one antenna is provided in at least one way selected from the group of ways including
said antenna is mounted on a ground plane,
said antenna is mounted on a circuit board,
said antenna is provided directly on a circuit board of said wireless device,
said antenna is printed directly on a circuit board of said wireless device,
said antenna is etched from a conducting layer of a circuit board of said wireless device,
said antenna is prepared by a thick film process,
said antenna is prepared by a thin film process, and
said antenna is embedded in an integrated circuit package that includes other parts of said wireless device.

64. The wireless device according to any of claims 62 or 63, **characterized in** that one, two, three or more or all feeding points (16a, 16b, 16c, 17, 18, 19) of said antenna are electrically connected to other electric circuits of said wireless device.

65. The wireless device according to any of claims 62 to 64 **characterized in** that one, two, three or more connections between said antenna and other parts of said wireless device are removed.

66. The wireless device according to any of claims 62 to 65, **characterized in** that one, two, three or more electrical switches are provided with which one, two, three or more feeding points (16a, 16b, 16c, 17, 18, 19) can be electrically connected to electrical circuits of said wireless device.

67. The wireless device according to any of claims 62 to 66, **characterized in** that said feeding points (16a, 16b, 16c, 17, 18, 19) can be electrically connected in different modes preferably in a mode selected from a group of modes including
simultaneously connecting two, three or more feeding points (16a, 16b, 16c, 17, 18, 19),
alternatively connecting only one at a time of said two, three or more feeding points (16a, 16b, 16c, 17, 18, 19), and
connecting different feeding points (16a, 16b, 16c, 17, 18, 19) at different times.

68. The wireless device according to any of claims 62 to 67, **characterized in** that one, two, three or more feeding points (16a, 16b, 16c, 17, 18, 19) are connected to ground of said wireless device.

69. The wireless device according to any of claims 62 to 68, **characterized in** that said conducting trace (15, 20) comprises separated parts, of which two, three or more are connected to each other by other parts than said antenna of said wireless device, preferably by an integrated circuit which is preferably provided on the same circuit substrate as said antenna.

70. The wireless device according to any of claims 62 to 69, **characterized in** that a space is provided between said antenna and any other member or constructive element of said wireless device or at least to the members surrounding said antenna and in particular between said antenna and the member of said wireless device to which said antenna is mounted.

71. The wireless device according to any of claims 62 to 70, **characterized in** that said wireless device comprises at least two, three or more antennae according to any of claims 1 to 20.

72. The wireless device according to any of claims 62 to 71, **characterized in** that said feeding points (16a, 16b, 16c, 17, 18, 19) which are not electrically connected are used for holding said antenna.

73. The wireless device according to any of claims 62 to 72, **characterized in** that said conducting trace (15, 20) is provided such, that it is not overlaying, or only partially overlaying, or not overlaid by, or only partially overlaid by a ground plane of said wireless device.

74. A wireless device comprising at least one SMD component (21) according to any of claims 21 to 41 or 61.

75. The wireless device according to claim 74, **characterized in** that said at least one SMD component (21) is provided in at least one way selected from the group of ways including said SMD component is mounted on a ground plane, said SMD component is mounted on a circuit board, and

said SMD component is embedded in an integrated circuit package that includes other parts of said wireless device.

76. The wireless device according to any of claims 74 or 75, **characterized in** that one, two, three or more or all access ports (16a, 16b, 16c, 17, 18, 19) of said SMD component (21) are electrically connected to other electric circuits of said wireless device.

77. The wireless device according to any of claims 74 to 76, **characterized in** that one, two, three or more connections between said SMD component (21) and other parts of said wireless device are removed.

78. The wireless device according to any of claims 74 to 77, **characterized in** that one, two, three or more electrical switches are provided with which one, two, three or more access ports (16a, 16b, 16c, 17, 18, 19) can be electrically connected to electrical circuits of said wireless device.

79. The wireless device according to any of claims 74 to 78, **characterized in** that said access ports (16a, 16b, 16c, 17, 18, 19) can be electrically connected in different modes preferably in a mode selected from a group of modes including simultaneously connecting two, three or more access ports (16a, 16b, 16c, 17, 18, 19), alternatively connecting only one at a time of said two, three or more access ports (16a, 16b, 16c, 17, 18, 19), and connecting different access ports (16a, 16b, 16c, 17, 18, 19) at different times.

80. The wireless device according to any of claims 74 to 79, **characterized in** that one, two, three or more access ports (16a, 16b, 16c, 17, 18, 19) are electrically connected to ground of said wireless device.

81. The wireless device according to any of claims 74 to 80, **characterized in** that said conducting trace (15, 20) comprises separated parts, of which two, three or more are connected to each other by other parts than said SMD component (21) of said wireless device, preferably by an integrated circuit which is preferably provided on the same circuit substrate as said SMD component (21).

82. The wireless device according to any of claims 74 to 81, **characterized in** that a space is provided between said SMD component (21) and any other member or constructive

element of said wireless device or at least to the members surrounding said SMD component (21) and in particular between said SMD component (21) and the member of said wireless device to which said SMD component (21) is mounted.

83. The wireless device according to any of claims 74 to 82, **characterized in** that said wireless device comprises at least two, three or more SMD components (21) according to any of claims 21 to 41.

84. The wireless device according to any of claims 74 to 83, **characterized in** that said access ports (16a, 16b, 16c, 17, 18, 19) which are not electrically connected are used for holding said SMD component (21).

85. The wireless device according to any of claims 74 to 84, **characterized in** that said conducting trace (15, 20) is provided such, that it is not overlaying, or only partially overlaying, or not overlaid by, or only partially overlaid by a ground plane of said wireless device.

86. A wireless device comprising at least one IC-package according to any of claims 42 to 61.

87. The wireless device according to claim 86, **characterized in** that said at least one IC-package is provided in at least one way selected from the group of ways including said IC-package is mounted on a ground plane, and said IC-package is mounted on a circuit board.

88. The wireless device according to any of claims 86 or 87, **characterized in** that one, two, three or more or all feeding purposes points (16a, 16b, 16c, 17, 18, 19) of said IC-package are electrically connected to other electric circuits of said wireless device.

89. The wireless device according to any of claims 86 to 88, **characterized in** that one, two, three or more connections between said IC-package and other parts of said wireless device are removed.

90. The wireless device according to any of claims 86 to 89, **characterized in** that one, two, three or more electrical switches are provided with which one, two, three or more feeding

purposes points (16a, 16b, 16c, 17, 18, 19) can be electrically connected to electrical circuits of said wireless device.

91. The wireless device according to any of claims 86 to 90, **characterized in** that said feeding purposes points (16a, 16b, 16c, 17, 18, 19) can be electrically connected in different modes preferably in a mode selected from a group of modes including simultaneously connecting two, three or more feeding purposes points (16a, 16b, 16c, 17, 18, 19), alternatively connecting only one at a time of said two, three or more feeding purposes points (16a, 16b, 16c, 17, 18, 19), and connecting different feeding purposes points (16a, 16b, 16c, 17, 18, 19) at different times.

92. The wireless device according to any of claims 86 to 91, **characterized in** that one, two, three or more feeding purposes points (16a, 16b, 16c, 17, 18, 19) are electrically connected to ground of said wireless device.

93. The wireless device according to any of claims 86 to 92, **characterized in** that said conducting trace (15, 20) comprises separated parts, of which two, three or more are connected to each other by the integrated circuit of said IC-package or by other parts than said IC-package of said wireless device such as another integrated circuit.

94. The wireless device according to any of claims 86 to 93, **characterized in** that a space is provided between said IC-package and any other member or constructive element of said wireless device or at least to the members surrounding said IC-package and in particular between said IC-package and the member of said wireless device to which said IC-package is mounted.

95. The wireless device according to any of claims 86 to 94, **characterized in** that said wireless device comprises at least two, three or more IC-packages according to any of claims 42 to 61.

96. The wireless device according to any of claims 86 to 95, **characterized in** that said feeding purposes points (16a, 16b, 16c, 17, 18, 19) which are not electrically connected are used for holding said IC-package.

97. The wireless device according to any of claims 86 to 96, **characterized in** that said conducting trace (15, 20) is provided such, that it is not overlaying, or only partially overlaying, or not overlaid by, or only partially overlaid by a ground plane of said wireless device.

98. The wireless device according to any of claims 62 to 97, **characterized in** that said wireless device is at least one selected from the group including a cellular phone, a handheld phone, a satellite phone, a multimedia terminal, a personal digital assistant (PDA), a portable music player, a radio, a digital camera, a USB dongle, a wireless headset, an ear phone, a hands-free kit, an electronic game, a remote control, an electric switch, a light switch, an alarm, a car kit, a computer card, a PCMCIA card, a sensor, a handset, a dongle, a computer interface, a computer mouse, a keyboard, a personal computer, a MP3 player, a portable DVD/CD player, a smoke detector, a switch, a motion sensor, a pressure sensor, a temperature sensor, a medical sensor, a meter, an alarm, a short/medium range wireless connectivity application, a Mini-PCI, a Notebook PC with WiFi module integrated, compact flash wireless cards, UART dongles, pocket PC with integrated Wi-Fi, access points for hot-spots.

99. The wireless device according to any of claims 62 to 98, **characterized in** that said wireless device is configured to operate in at least one wireless communication system preferably selected from the group including Bluetooth, 2.4 GHz Bluetooth, 2.4 GHz IEEE802.11b/g, 5 GHz IEEE802.11a, Hyperlan, IEEE802.11 (WiFi), ultra wide band (UWB), Wimax, ZigBee, ZigBee at 860 MHz, ZigBee at 915 MHz, GPS, GPS at 1.575 GHz, GPS at 1.227 GHz, Galileo, GSM-900, DCS-1800, UMTS, CDMA, DBA, WLAN, WLAN at 2.4 GHz – 5 GHz, PCS1900, KPCS, WCDMA, DAB, 2.4 – 2.483 GHz band, and 2.471 – 2.497 GHz band.

100. A method for contacting an antenna according to any of claims 1 to 20 or 61 and/or an SMD component according to any of claims 21 to 41 or 61 and/or an IC-package according to any of claims 42 to 61,
wherein said conducting trace (15, 20) is contacted at one, two, three or more points (16a, 16b, 16c, 17, 18, 19).

101. The method for contacting according to claim 100, **characterized in** that one, two, three or more contacts to said conducting trace (15, 20) are removed.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/EP2005/054297

A. CLASSIFICATION OF SUBJECT MATTER

H01Q1/38 H01Q9/16 H01Q9/28

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

H01Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data, PAJ

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category °	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 03/050913 A (FRACTUS, S.A; ORTIGOSA VALLEJO, JUAN-IGNACIO; PUENTE BALIARDA, CARLES) 19 June 2003 (2003-06-19) page 7, lines 17-30; claim 1; figures 4-6	1-101
X	----- WO 01/54225 A (FRACTUS, S.A; PUENTE BALIARDA, CARLES; ROZAN, EDOUARD, JEAN, LOUIS; AN) 26 July 2001 (2001-07-26) page 10, line 11 - page 11, line 18; claim 1; figure 3	1-101
X	----- WO 2004/042868 A (FRACTUS, S.A; SOLER CASTANY, JORDI; ANGUERA PROS, JAUME; PUENTE BALIAR) 21 May 2004 (2004-05-21) claim 1; figure 7 -----	1-101

☐ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

° Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance
 "E" earlier document but published on or after the international filing date
 "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
 "O" document referring to an oral disclosure, use, exhibition or other means
 "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
 "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
 "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
 "&" document member of the same patent family

Date of the actual completion of the international search

INTERNATIONAL SEARCH REPORT

International application No.
PCT/EP2005/054297

Box II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1 (first option) , 2-99 , 100-101, insofar as these claims are....

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1 (first option), 2-99, 100-101, insofar as these claims are dependent on or referring to the first option mentioned in claim 1

directed to a space-filling curve

2. claims: 1 (second option), 2-99, 100-101, insofar as these claims are dependent on or referring to the second option mentioned in claim 1

directed to a grid-dimension curve

3. claims: 1 (third option), 2-99, 100-101, insofar as these claims are dependent on or referring to the third option mentioned in claim 1

directed to a box-counting curve

4. claims: 1 (fourth option), 2-99, 100-101, insofar as these claims are dependent on or referring to the fourth option mentioned in claim 1

directed to a contour curve

5. claims: 1 (fifth option), 2-99, 100-101, insofar as these claims are dependent on or referring to the fifth option mentioned in claim 1

directed to a shape of a multilevel structure
